PAPER

Toward an Understanding of Musical Factors in Judging a Song on First Listen*

Kosetsu TSUKUDA[†a)], **Tomoyasu NAKANO**[†b)], **Masahiro HAMASAKI**[†c)], ***Nonmembers***, ***and*** **Masataka GOTO**[†d)], ***Fellow***

SUMMARY When a user listens to a song for the first time, what musical factors (*e.g.*, melody, tempo, and lyrics) influence the user's decision to like or dislike the song? An answer to this question would enable researchers to more deeply understand how people interact with music. Thus, in this paper, we report the results of an online survey involving 302 participants to investigate the influence of 10 musical factors. We also evaluate how a user's personal characteristics (*i.e.*, personality traits and musical sophistication) relate to the importance of each factor for the user. Moreover, we propose and evaluate three factor-based functions that would enable more effectively browsing songs on a music streaming service. The user survey results provide several reusable insights, including the following: (1) for most participants, the melody and singing voice are considered important factors in judging whether they like a song on first listen; (2) personal characteristics do influence the important factors (*e.g.*, participants who have high openness and are sensitive to beat deviations emphasize melody); and (3) the proposed functions each have a certain level of demand because they enable users to easily find music that fits their tastes. We have released part of the survey results as publicly available data so that other researchers can reproduce the results and analyze the data from their own viewpoints.

key words: *musical factor, music preference, user survey, personality trait, musical sophistication*

1. Introduction

When a user listens to a song for the first time on a music streaming service and it matches her/his taste, s/he may listen to it until the end or add it to her/his favorites or a playlist. On the other hand, if the song does not match the user's preferences, s/he may stop playing it partway through [2], [3]. By accumulating logs of such listening behaviors, music streaming services can estimate users' music preferences and implement functions such as recommendations [4], [5].

However, when a user first listens to a song and decides whether or not s/he likes it, which musical factors does s/he consider important? For example, one user may like a song because of its lyrics, another may like it because of its melody, and third may like it because of the sound of a musical instrument. Several prior studies investigated people's preferred musical factors [6]–[8]. However, those studies targeted songs that the study participants already liked and investigated the reasons for liking those songs in terms of factors that were specific to the songs. Accordingly, when a participant answered that s/he liked a certain song because of its lyrics, it was unclear that s/he would always judge whether s/he liked or disliked a song because of its lyrics. Thus, despite those studies, there is a lack of research on the musical factors that influence people's judgment on whether they like a song on first listen. This lack of research motivates our first research question:

RQ1 When people listen to a song for the first time and judge whether they like it, which musical factors affect this judgment, and to what extent?

To more deeply understand how people interact with music, the effects of users' personality traits and musical sophistication on their music preferences and listening behaviors have also been studied [6], [9]–[22]. For example, it has been reported that people with high openness tend to show a preference for folk music [9] and that musical sophistication positively influences recommendation acceptance [10]. Following such studies, we address the second research question:

RQ2 How do people's personality traits and musical sophistication affect the importance of each musical factor in judging whether they like a song?

If a certain musical factor influences judgments about song preferences, it would be useful to propose practical examples of its engineering use. In fact, proposed improvements to the functions of music streaming services from user study results have provided useful insights to the research community [23]–[36]. Hence, we investigate a third research question:

RQ3 What are the implications of musical factors for the functions of music streaming services?

To address these research questions, we targeted 10 musical factors and conducted a questionnaire-based online user survey involving 302 participants. Our main contributions can be summarized as follows.

- We reveal that the factors of *melody* and *singing voice* have large influences on music preference judgment, whereas the factor of *danceability* has a small influence.

Manuscript received June 10, 2024.
Manuscript revised November 11, 2024.
Manuscript publicized January 17, 2025.

- From a psychological perspective, we show that both personality traits and musical sophistication affect the importance of the various musical factors. Given these results, we discuss the possibility that the important factors for a particular user could be estimated from the user's listening behaviors on a music streaming service.
- From an engineering perspective, we propose three functions that would enable users to effectively browse songs by leveraging musical factors, and we show that each function has a certain level of demand.
- We have made the English translation of the survey questionnaire and the survey results publicly available on the web to support future studies[†].

2. Related Work

2.1 Musical Factors

Understanding why people listen to music has been of interest to researchers. One typical research direction focuses on the motivation to listen to music in daily life. The main reasons include emotional reasons such as relaxation [21], [37]–[40] and relief [41], [42]. People also listen to music to concentrate and to pass time [43].

Another research direction investigates the reasons for listening to specific preferred songs in terms of musical factors. Greasley et al. [7] conducted interviews about participants' music collections. Among the main reasons why the participants liked their collections were musical factors such as the lyrics and instruments. Sanfilippo et al. [8] asked participants to sample two songs from their music library on a listening device and answer questions such as "why do you enjoy listening to the track?" The participants often answered the questions by using a vocabulary of musical factors. Boyle et al. [6] investigated the influence of musical factors on young people's pop music preferences. Each participant listed her/his three favorite pop songs and rated the importance of various musical factors in liking those songs. The results revealed that melody, mood, and rhythm had large influences. Although these studies investigated the influences of musical factors, they focused on only songs that the participants already liked. Our study is different in that we focus on the musical factors that people consider important when they listen to a song for the first time. Since there is a vast number of songs that people have not yet listened to, investigating such factors is beneficial to support finding songs that match their preferences.

2.2 Personal Characteristics

In the music domain, user's preferences, interests, and behaviors are influenced by personal characteristics. In particular, many studies have investigated the influences of personality traits measured by the Big Five Inventory [9], [11]–[18], [44]–[48]. For example, personality has significant associations with genre preferences [9], [14]–[16], [44] and audio preferences [46]. It also influences the desired level of diversity in a recommended song list [47]. Ferwerda et al. [48] revealed that when a user browses for music, the preferred taxonomy (mood, activity, and genre) depends on the user's personality. Such personality-based results can be used for personalization. In fact, several studies have shown increased recommendation quality when personality is incorporated [49]–[52]. Musical sophistication is another typical personal characteristic that influences music preferences. For example, musically sophisticated users listen to more diverse songs on both the artist and genre levels [53], are more familiar with the songs in a recommended song list [54], and prefer a less personalized playlist [19]. These findings can also be used to improve music recommendations and user interfaces. Following those studies, we investigate the influences of personality traits and musical sophistication on the importance of musical factors, and we suggest how its results can be used to improve the recommendations.

2.3 Design and Function Proposals

For user studies on music listeners' needs, preferences, and behaviors, it is common to not only report the results but also propose designs and functions to improve music services by applying the results [23]–[36]. Such proposals have provided reusable insights for the research community. Examples of these proposals include song recommendations according to the user's attention level [23], support for remote co-listening with a friend [24], and support for users to add their interpretations of lyrics [25]. Inspired by those prior studies, we propose three functions that enable music streaming services to leverage musical factors. Whereas the above studies only proposed designs and functions, we also conducted a user study to evaluate users' willingness to use the proposed functions.

3. Methods

3.1 Participants

We recruited participants for our user study via an online research company in Japan. We limited the participants to those who were Japanese and listened to music an average of at least one day per week via any music streaming service. The participants answered our questionnaire through a web browser. We paid about 11.26 USD (1,750 JPY) to each participant. Although 354 participants answered the survey, to make the analysis results more reliable, we removed the answers from 52 participants who submitted improper responses to a free-response question[††]. The remaining 302 participants were diverse in both gender and age range: 147

[†]They can be downloaded from https://github.com/ktsukuda/musical_factor.

[††]We also examined the responses to multiple-choice questions and confirmed that no participants selected the same answer number for all questions. Therefore, we did not remove any participants based on their multiple-choice responses.

male (10s: 4; 20s: 31; 30s: 33; 40s: 44; 50s: 35) and 155 female (10s: 9; 20s: 39; 30s: 35; 40s: 34; 50s: 38).

3.2 Influence of Musical Factors

3.2.1 Musical Factors

Referring to prior studies on people's favorite songs [6]–[8], [55], we targeted the following 10 musical factors that may influence a person's judgment of liking or disliking music on first listen: *melody*, *singing voice*, *rhythm*, *lyrics*, *mood*, *tempo*, *harmony*, *sentiment*, *instruments*, and *danceability*. Although these 10 factors are not completely independent each other (*e.g.*, there would be relatively high correlation between *mood* and *sentiment*), we adopted them to analyze as many factors as possible. In this study, all of these factors were determined entirely from the music. That is, we did not consider social factors that depend on the context of the music or the listener (*e.g.*, the artist's image, the popularity of music, and whether music was introduced by a friend). Rather, as this is an initial study on the influence of musical factors for judging a song on first listen, we leave the investigation of such social factors for future work.

3.2.2 Procedure

For each musical factor, we first showed the participants the factor's name, its meaning, and a question. In the case of *instruments*, for example, we showed the following description to represent its meaning: "*Instruments* means the type of instruments used in the piece and their sounds." Similarly, we showed the following question: "How important is the *instruments* in judging whether you like or dislike a song on first listen?"[†] The possible answers were "not important," "hardly important," "somewhat important," "important," and "very important." When the answer for a factor was "not important" or "hardly important," the participant was asked to respond freely on why it was unimportant. On the other hand, when the answer was "somewhat important," "important," or "very important," the participant was asked to respond freely with at least one criterion for judging that s/he liked or disliked a song according to the factor. The 10 musical factors were displayed in a random order to each participant.

Note that in this survey, we asked the participants to answer the questions without actually listening to music to avoid answer bias caused by the music they listened to for the survey. Instead, they were asked to imagine daily situations where they listen to a song for the first time and rate the importance of each factor. This type of survey, which involves imagining a certain situation, is an established survey method in music-related studies [23], [24], [56]–[60].

3.3 Influence of Personal Factors

To enable a more detailed analysis of musical factors from a psychological perspective, we conduct a survey based on personality traits and musical sophistication.

3.3.1 Procedure for Personality Traits

We measured the participants' personality traits in terms of five aspects (*i.e.*, *openness*, *conscientiousness*, *extraversion*, *agreeableness*, and *neuroticism*) by using the 29-item Big Five Inventory (BFI) on a 7-point scale (1: strongly disagree - 7: strongly agree) [61]. We used the BFI because of its popularity in past studies [9], [11]–[18], [44]–[48] compared to other traits such as opinion leadership [20].

3.3.2 Procedure for Musical Sophistication

To measure the musical sophistication, we used the following nine questions on a 7-point scale.

1. InstExp: I engage in regular, daily practice of a musical instrument (1: never; 2: less than 1 year; 3: 1-2 years; 4: 2-4 years; 5: 4-6 years; 6: 6-10 years; 7: 10 or more years).
2. DanceExp: I engage in regular, daily dancing (1: never; 2: less than 1 year; 3: 1-2 years; 4: 2-4 years; 5: 4-6 years; 6: 6-10 years; 7: 10 or more years).
3. NoticeBeat: I can tell when people sing or play out of time with the beat (1: strongly disagree; 2: disagree; 3: somewhat disagree; 4: neither agree nor disagree; 5: somewhat agree; 6: agree; 7: strongly agree).
4. NoticeTune: I can tell when people sing or play out of tune (1: strongly disagree; 2: disagree; 3: somewhat disagree; 4: neither agree nor disagree; 5: somewhat agree; 6: agree; 7: strongly agree).
5. LsnMusic: I listen to music (1: less than 15 minutes per day; 2: 15-30 minutes per day; 3: 30-60 minutes per day; 4: 1-1.5 hours per day; 5: 1.5-2 hours per day; 6: 2-4 hours per day; 7: more than 4 hours per day).
6. LsnNew: I listen to music that is new to me (1: less than 1 song per month; 2: 1-3 songs per month; 3: 4-6 songs per month; 4; 7-10 songs per month; 5: 11-20 songs per month; 6: 21-30 songs per month; 7: more than 30 songs per month).
7. ViewLyrics: I view lyrics while listening to music (1: less than 1 song per month; 2: 1-3 songs per month; 3: 4-6 songs per month; 4; 7-10 songs per month; 5: 11-20 songs per month; 6: 21-30 songs per month; 7: more than 30 songs per month).
8. Karaoke: I sing karaoke (1: less than 1 time per year; 2: 1-2 times per year; 3: 3-5 times per year; 4: 6-11 times per year; 5: 1-3 times per month; 6: 1-3 times per week; 7: more than 3 times per week).
9. AttEvt: I attend live music events as an audience member (1: less than 1 time per year; 2: 1 time per year; 3: 2 times per year; 4: 3 times per year; 5: 4-6 times per year; 6: 7-10 times per year; 7: more than 10 times per year).

Questions 1, 3, 4, 5, and 9 derive from the Goldsmiths

[†]In this survey, no specifications were made regarding the genre of the song.

Fig. 1 Overview of the three proposed functions. In the user study, these images were presented to the participants.

Musical Sophistication Index (Gold-MSI) [62]. In addition, we asked four questions of our own (questions 2, 6, 7, and 8). For questions 5-9, we asked the participants to give the average frequencies of those behaviors.

3.4 Functions Based on Musical Factors

To enable a more detailed analysis of musical factors from an engineering perspective, we propose three functions, illustrated in Fig. 1, that could enrich and diversify the music listening experience on streaming services. We also investigate the usefulness of these functions. In this subsection, we first explain each of the three functions, followed by a description of the survey procedure.

3.4.1 Function 1: Registration of Factor Importance

With this function, shown in Fig. 1 (a), users register the importance of each of the 10 musical factors on a 5-point scale when judging whether they like or dislike music on first listen. It is not necessary to register the importance of all factors. For example, the importance of *rhythm* is not registered in Fig. 1 (a). The registration process only needs to be done once, and the registered information can be changed later.

This function supports the users as follows. Suppose that a user is listening to her/his favorite song s. The user has registered *lyrics* as "very important" and *tempo* as "hardly important." Hence, among songs that are new to this user, we can recommend songs that have various tempos and similar lyrics to s. By listening to the recommended songs, the user can find new favorite songs.

3.4.2 Function 2: Evaluation of Songs by Factors

This proposed function allows users to rate their song preferences on a factor-by-factor basis, as shown in Fig. 1 (b). The ratings are not mandatory: users only need to rate the songs that they want to rate. In addition, they do not need to rate songs in terms of all 10 factors. For example, in the figure, the user does not rate *mood*. For each song, by computing the average value of all users' rating results for each factor, we can display others' evaluations (averaged ratings) like those shown in Fig. 1 (b).

This function supports the users as follows. Suppose that a user is interested in an artist named "Betty," and that *danceability* is an important factor for the user. Then, songs by "Betty" can be sorted and displayed in order of the averaged ratings for *danceability*. This enables efficient discovery of songs that match the user's preferences.

3.4.3 Function 3: Presentation of Factor Information

With this function, information on factors that a user wants to know for a song is displayed as shown in Fig. 1 (c). The information on each of the 10 factors can be automatically estimated by using techniques from existing studies [63]–[69]. Thus, unlike the two previous functions, this one does not require the user to input any information.

This function supports the users as follows. When a user checks a list of newly released songs, usually only basic information such as the artist and title is displayed for each song. In contrast, our proposed function can display information on the musical factor for each song. For example, if the user prefers slow-tempo songs with piano, s/he can listen only to such songs by referring to the displayed information on *tempo* and *instruments*. This allows the user to efficiently find songs that match her/his preferences among a vast number of new songs.

3.4.4 Procedure

For each function, we showed the participants an overview of the function and examples of the user support that the function would enable as we described above[†]. The participants were asked to indicate their willingness to use the function, on a 5-point scale ("unwilling," "not very willing," "undecided," "reasonably willing," and "willing"), if it were implemented on the music streaming service that they used regularly. They were also asked to provide free responses on their willingness. The three functions were displayed in a random order to each participant.

4. Results for Influence of Musical Factors

Figure 2 shows the importance distribution for each factor. We can see that the importance was high for *melody* and *singing voice*; in fact, paired Wilcoxon signed-rank tests with Bonferroni correction revealed that their medians (*i.e.*, 4) were statistically higher than the medians of the remaining eight factors at $p < 0.01$[††]. Among the remaining eight

[†]We leave it as future work to actually implement these functions and conduct a long-term user study on them including how to visualize the information.

[††]The details of the significance test results are provided in Appendix.

Table 1 Top three criteria for judging "like" and "dislike," for each musical factor. Each number in parentheses indicates the number of participants who responded with the corresponding criterion.

Factor		1st	2nd	3rd
Melody	Like (265)	Easy to remember (35)	Easy to sing or hum (33)	Feels comfortable (28)
	Dislike (193)	Too loud (18)	Difficult to sing or hum (16)	Feels uncomfortable (15)
Singing voice	Like (261)	Specific type (beautiful, powerful, soft, etc.) (74)	Voice to my liking (54)	Feels comfortable (51)
	Dislike (203)	Feels uncomfortable (50)	Specific type (raspy, piercing, etc.) (47)	Voice not to my liking (28)
Rhythm	Like (237)	Groovy (53)	Feels comfortable (23)	Rhythm to my liking (19)
	Dislike (167)	Rhythm not to my liking (17)	Slow (16)	Not groovy (15)
Lyrics	Like (218)	Sympathetic (71)	Inspirational (41)	Positive (10)
	Dislike (164)	Unclear meaning (41)	Lack empathy (30)	Pedestrian (26)
Mood	Like (219)	Cheerful (51)	Fits my mood/situation (25)	Calm (21)
	Dislike (162)	Gloomy (32)	Too loud (29)	Feels uncomfortable (12)
Tempo	Like (220)	Fast (40)	Groovy (29)	Feels comfortable (24)
	Dislike (163)	Slow (48)	Fast (31)	Feels uncomfortable (15)
Harmony	Like (174)	Feels comfortable (43)	Beautiful (23)	Harmonious (22)
	Dislike (116)	Feels uncomfortable (25)	Monotonous (7)	Inharmonious (6)
Sentiment	Like (163)	Positive (33)	Inspirational (30)	Sympathetic (25)
	Dislike (114)	Negative (32)	Evokes no emotion (12)	Doesn't fit my mood/situation (7)
Instruments	Like (146)	Include specific instruments (24)	Fit the song (17)	Feel comfortable (15)
	Dislike (102)	Too loud (24)	Feel uncomfortable (11)	Don't fit the song (7)
Danceability	Like (66)	Body moves naturally to music (13)	Groovy (11)	Rhythmic (9)
	Dislike (46)	Not groovy (6)	Gloomy (5)	Rhythm is bad (4)

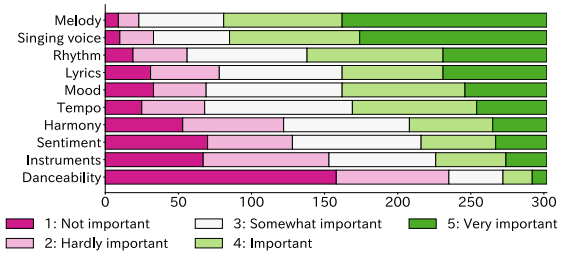

Fig. 2 Importance distributions of musical factors (x-axis: number of participants).

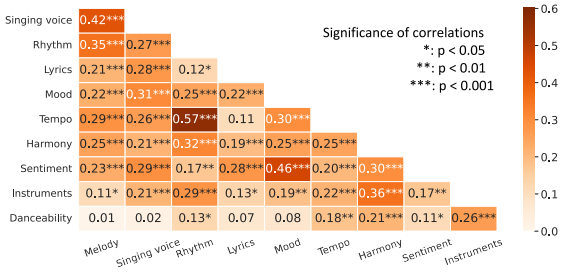

Fig. 3 Spearman's rank correlations of importance between musical factors.

factors, more than half of the participants gave a rating of 3, 4, or 5 for *rhythm*, *lyrics*, *mood*, *tempo*, *harmony*, and *sentiment*. To more deeply understand the relationships between factors, we show the Spearman's rank correlations between them in Fig. 3. There were high (> 0.4) correlations between *rhythm* and *tempo*, *mood* and *sentiment*, and *melody* and *singing voice*. Although *lyrics* had a relatively high average importance, it had low (< 0.3) correlations with all other factors. *Danceability*, which had the lowest average importance, showed a similar tendency.

For each factor, to analyze the free responses on criteria for liking a song, the first author, who is an expert in music information processing, manually grouped the responses. Because we allowed the participants to give more than one criterion, each participant's response could be assigned to more than one group. Similarly, the first author grouped the responses on criteria for disliking a song and reasons for the unimportance of certain factors. Here, we omit the reasons for unimportance, because the most common response for all factors was "I am not interested in this factor." On the other hand, the criteria for liking or disliking a song were diverse, as seen in Table 1, which lists the top three criteria for each factor in terms of the group size. Many criteria involved opposite terms for liked and disliked songs: in the case of *tempo*, for example, participants who gave "fast" as a criterion for liking a song tended to give "slow" as a criterion for disliking a song. In addition, the second column indicates that, for all factors, more participants gave criteria for liking a song than for disliking a song, which means that it was more common to have criteria for liking a song than to have criteria for disliking a song. An interesting application of this finding would be to use criteria for liking a song in explainable recommendation. For example, when a song is recommended to a user who emphasizes *melody*, s/he may be more willing to listen to it if it appears with an explanation such as "this song is recommended to you because the melody is easy to remember."

The results in Fig. 2 are somewhat similar to those reported by Boyle et al. [6] (*e.g.*, *melody* and *rhythm* had high importance, while *danceability* had low importance). Here, note that the purpose of this study is not to clarify the difference between the "important musical factors for songs that people have previously listened to and already liked," as targeted by previous studies, and the "important musical factors for songs that people listen to for the first time," as targeted by this study. Rather, the fact that commonalities can be observed between the two is also one of the important research insights.

Finally, since people's music preferences can be influenced by the context in which they listen to it, the impor-

tant musical factors may vary depending on the context [70]. However, as shown in Sect. 3.1, there is no significant bias in the age or gender of participants in this study, indicating that the contexts assumed by the participants when responding were diverse, rather than being skewed toward any particular scenario, such as commuting, studying, or working. Therefore, the findings of this study can be interpreted as generalized results in terms of music listening contexts.

5. Results for Influence of Personal Factors

5.1 Results for Personality Traits

Table 2 lists the Spearman's rank correlations between the personality traits and the importance of each musical factor. Following existing studies that analyzed the correlation between personal factors and music consumption tendencies [9], [11], [12], [14], [15], [44], [46], we discuss our findings based on the significance of the correlation coefficients. *Openness* had significant correlations with as many as seven factors. That is, participants with higher *openness* had more diverse criteria for judging whether a song fits their taste. This result is similar to a previous finding that people with high *openness* tended to listen to more diverse songs in terms of genres [9]. Similarly, *extraversion* also had significant correlations with many factors, particularly, *danceability*. This result echoes a report that people with high *extraversion* tended to listen to songs with high danceability on a music streaming service [52]. *Conscientiousness* was the only trait that had a significant correlation with *sentiment*. Both *agreeableness* and *neuroticism* had significant correlations with as few as two factors. These results are similar to a previous finding that those traits showed significant correlations with few genres [9].

Prior studies correlated personality traits with genre preferences and music audio preferences [9], [46]. For example, people who often listen to folk music were found to have high *openness* [9]. As seen in Table 2, people with high *openness* emphasize *lyrics*; accordingly, for a user who often listens to folk songs, it would be helpful to recommend songs according to the similarity of lyrics.

5.2 Results for Musical Sophistication

Figure 4 and Table 3 show the distribution of musical sophistication and the Spearman's rank correlations between musical sophistication and the importance of each musical factor, respectively. Similar to Sect. 5.1, we discuss our findings based on the significance of the correlation coefficients. Overall, many of the results matched our intuition. For example, DanceExp had a significantly high correlation with *danceability*; participants who were sensitive to beat and tune deviations emphasized audio-based factors such as *melody*, *singing voice*, and *harmony*; and ViewLyrics had the highest correlation with *lyrics*. It is also convincing that participants

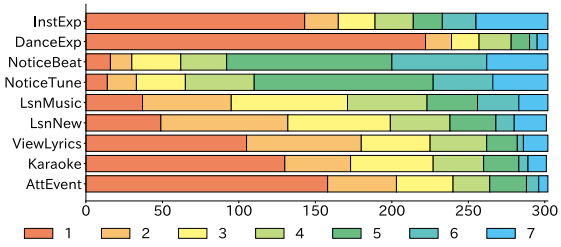

Fig. 4 Distribution of musical sophistication. The specific response options from 1 to 7 are described in Sect. 3.3.2.

Table 2 Spearman's rank correlations between personality traits and musical factor importance (N=302). Significant correlations are shown in bold (*: p< 0.05; **: p< 0.01; ***: p< 0.001). M and SD stand for the mean and standard deviation of personality traits, respectively.

Table 4 Top three free-response reasons for "reasonably willing" or "willing" to use each of the proposed functions. Each number in parentheses indicates the number of participants who gave that reason.

	Function 1: registration of factor importance	Function 2: evaluation of songs by factors	Function 3: presentation of factor information
1st	Easy to find music that fits my taste. (46)	Would like to refer to others' evaluations. (22)	Easy to find music that fits my mood/situation. (27)
2nd	Helpful for listening to new songs. (33)	Easy to understand others' evaluations. (14)	Easy to find music that fits my taste. (26)
3rd	Looks interesting to use. (11)	Easy to find music that fits my taste. (13)	Helpful for listening to new songs. (16)

who often sang karaoke emphasized *lyrics*; those who often attended live music events emphasized both *lyrics* and *danceability*; and InstExp had a significant correlation with *harmony*. Table 3 also indicates certain high correlations that are not obvious (*e.g.*, between LsnMusic/LsnNew and *lyrics* and between LsnNew and *danceability*).

Certain metrics, such as LsnMusic, LsnNew, and ViewLyrics, can be computed for each user on a music streaming service [60], [71], [72]. Thus, the results in Table 3 can also be used to increase the confidence in estimating the importance of each factor to a user without explicitly asking the importance. For example, if a user often listens to folk music (*i.e.*, the user would have high *openness* as has been reported by Ferwerda et al. [9]) and new songs, we can estimate from the results in Tables 2 and 3 that *rhythm* is one of the user's important factors. Hence, the user would be more likely to accept recommendations by recommending songs according to the similarity of their rhythms.

6. Results for Functions Based on Musical Factors

Figure 5 shows the answer distribution for each function. Functions 1 and 3 were more positively received than function 2. To analyze the results, the first author manually grouped negative responses (*i.e.*, the free responses for "unwilling" and "not very willing"). As we had anticipated, a reason of "I do not need the function" was common for all three functions. Regarding function 2, although we explained that the ratings were not mandatory, a response of "It is tedious to rate songs" was also common. This is why the distribution for function 2 was more biased in the negative direction. Here, note that our goal was not to propose functions that all participants would be willing to use. Rather, we sought to confirm that the proposed functions would have a certain level of demand; accordingly, the results in Fig. 5 indicate that we achieved our objective.

The first author also manually grouped the positive responses (*i.e.*, the free responses for "willing" and "reasonably willing"). Table 4 lists the top three responses in terms of the group size for each function. We can see that, in general, the participants tended to appreciate functions that would make it easy to find music that fits their taste (all functions) and easy to listen to new songs (functions 1 and 3). The responses for function 2 also indicate that they were interested in referring to other users' evaluations of a song. We can also see that the participants felt it was valuable to be able to find music according to their mood or situation (function 3). These responses provide reusable insights for later studies: when researchers or streaming services propose a new function, such user demand could serve as a useful guideline for its design.

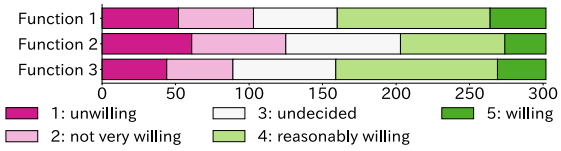

Fig. 5 Distribution of the willingness to use each of the proposed functions (x-axis: number of participants).

If function 3 were implemented on a music streaming service, it might be difficult to estimate the information for all factors because of the platform's resource limitations. In such a case, a possible solution would be to decrease the number of displayed factors according to the results shown in Fig. 3. For example, *rhythm* information could be omitted, because *tempo* has a high correlation with *rhythm*, and users who emphasize *rhythm* could thus refer to *tempo* information instead. In contrast, *lyrics* should not be eliminated because it has low correlations with the other factors, and there would not be no alternative factor for users who emphasize *lyrics*.

7. Conclusion

In this paper, we conducted an online user survey involving 302 participants. The reusable insights obtained from our user survey can be summarized as follows.

- We showed that the *melody* and *singing voice* are considered important for most participants. Because there were trends in the criteria for each factor, as seen in Table 1, the criteria could be used to increase the explainability of song recommendations, as discussed in Sect. 4.
- Personality and musical sophistication influence the importance of each musical factor. As discussed in Sects. 5.1 and 5.2, these results would be useful for estimating which factors are important to a user from the user's listening behaviors on a streaming service.
- The evaluation results for our proposed functions show that there is a certain demand for functions that enable users to browse songs according to musical factors. The reasons for each function's demand in Table 4 could provide guidelines for other researchers and services to propose novel factor-based functions.

Finally, since the participants in our user study were Japanese, we acknowledge the limitation of this study in that not all of the findings can be generalized. For example, as shown in Fig. 2, the importance of *danceability* was low, but

this may be due to the fact that most Japanese people do not have the habit of dancing while listening to music on a daily basis, as indicated in Fig. 4. In Western countries, where more people are likely to have such a habit, the importance of *danceability* would be higher. Nevertheless, we believe that our study provides a worthwhile contribution as a first step toward understanding how musical factors influence whether people like a song on first listen. At the same time, the above limitation can guide future work such as investigating the differences in important musical factors among countries and cultures. The publicly available dataset of results from our user study will enable researchers not only to perform such comparisons but also to analyze and compare results from different viewpoints.

Appendix: Statistical Tests of Importance Differences between Musical Factors

Table A· 1 shows the details of the significance test results regarding *melody* and *singing voice*. In Sect. 4, as statistical tests were conducted for arbitrary pairs of musical factors, the corrected alpha value is $\frac{0.01}{{}_{10}C_2} = 2.22 \times 10^{-4}$. As shown in Table A· 1, there were no results indicating negligible effect sizes ($-0.1 <$ effect size ≤ 0). Specifically, two tests exhibited small effect sizes ($-0.3 <$ effect size ≤ -0.1), 12 tests showed moderate effect sizes ($-0.5 <$ effect size ≤ -0.3), and two tests demonstrated large effect sizes (effect size ≤ -0.5). Therefore, it was confirmed that the small p-values were not merely due to the large sample size; the effect sizes also indicated fundamental differences in the importance of *melody* and *singing voice* compared to the importance of the other eight musical factors.

Table A· 1 Details of the significance test results regarding *melody* and *singing voice*.

Factor 1	Factor 2	Z-statistic	p-value	effect size
Melody	Rhythm	−7.30	2.87×10^{-13}	−0.297
Melody	Lyrics	−8.04	9.06×10^{-16}	−0.327
Melody	Mood	−8.48	2.24×10^{-17}	−0.345
Melody	Tempo	−9.10	8.67×10^{-20}	−0.371
Melody	Harmony	−11.63	2.87×10^{-31}	−0.473
Melody	Sentiment	−11.79	4.49×10^{-32}	−0.480
Melody	Instruments	−12.10	1.08×10^{-33}	−0.492
Melody	Danceability	−13.83	1.60×10^{-43}	−0.563
Singing voice	Rhythm	−5.74	9.35×10^{-9}	−0.234
Singing voice	Lyrics	−7.44	9.85×10^{-14}	−0.303
Singing voice	Mood	−7.90	2.83×10^{-15}	−0.321
Singing voice	Tempo	−7.98	1.49×10^{-15}	−0.325
Singing voice	Harmony	−10.75	5.80×10^{-27}	−0.438
Singing voice	Sentiment	−11.51	1.18×10^{-30}	−0.468
Singing voice	Instruments	−11.85	2.05×10^{-32}	−0.482
Singing voice	Danceability	−13.60	3.83×10^{-42}	−0.554

Kosetsu Tsukuda received the Ph.D. degree in Informatics from Kyoto University, Japan in 2014. He is currently a Senior Researcher at the National Institute of Advanced Industrial Science and Technology (AIST), Japan. His research interests lie in the areas of recommender systems and user behavior analysis regarding user-generated content and music content.

Tomoyasu Nakano received the Ph.D. degree in Informatics from University of Tsukuba, Tsukuba, Japan in 2008. He is currently working as the leader of the Media Interaction Group, National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan. His research interests include singing information processing, human-computer interaction, and music information retrieval. He has received several awards including the IPSJ Yamashita SIG Research Award from the Information Processing Society of Japan (IPSJ), the Best Paper Award from the Sound and Music Computing Conference 2013, and the Honorable Mention Poster Award from the IEEE Pacific Visualization Symposium 2018. He is a member of the IPSJ and the Acoustical Society of Japan.

Masahiro Hamasaki received the Ph.D. degree in informatics from the Graduate University for Advanced Studies (SOKENDAI), Japan in 2005. He is currently a Senior Planning Manager at the National Institute of Advanced Industrial Science and Technology (AIST), Japan. His research interests include Web mining, semantic Web, and social media analysis. He is a member of the JSAI, the IPSJ, and ACM.

Masataka Goto received the Doctor of Engineering degree from Waseda University in 1998. He is currently a Senior Principal Researcher at the National Institute of Advanced Industrial Science and Technology (AIST), Japan. Over the past 32 years he has published more than 300 papers in refereed journals and international conference proceedings and has received 69 awards, including several best paper awards, best presentation awards, the Tenth Japan Academy Medal, and the Tenth JSPS PRIZE. He has served as a committee member of over 120 scientific societies and conferences, including as the General Chair of ISMIR 2009 and 2014. As the research director, he began the OngaACCEL project in 2016 and the RecMus project in 2021, which are five-year JST-funded research projects (ACCEL and CREST) related to music technologies.
